A Relational Theorem on the Correctness of General Recursive Programs

Context

Context

- Identify programs and specifications with their associated input-output relations on a space state Σ.
- A programming theory may be developed within the framework of Tarski's relational calculus where programs and specifications (possibly non-deterministic) are considered as logical predicates.
- Look at *recursive program definitions* as *fixed point equations* associated to *relational operators*, whose solutions include the input-output relations corresponding to such programs.
- Conditions (boolean expressions on Σ) correspond to relations whose domains coincide with the set of those initial states in which the condition holds, and which relates each member of its domain onto any final state whatsoever.

Continuous Operators

According to Knaster-Tarski theorem for a continuous relational operator f (function from relations to relations on Σ) the equation X = f.X has a solution on Σ (a complete lattice).

There may be many solutions; the least of them is μf , the least fixed point of the operator f.

The continuity of f implies that μf can be constructed as the union of a series of approximations obtained by its iteration:

$$\mu f = \bigcup_{n>0} f^n \cdot O$$

where $f^{0.R} = R$ and $f^{n+1.R} = f(f^{n.R})$ for all $n \ge 0$ and relation R. Context

The Correctness Problem for a Recursive Program

Correctness Problem

Given the program (by its source text) which computes a function f with domain D ($D \subseteq \Sigma$) and given its specification in terms of a predicate S describing the desired relationship between its initial and final values, *find* non restrictive *regularity conditions* on its text to prove it correct with respect to S by a well-founded induction on a covering of D.

2 Regular Operators

3 Correctness of Regular Recursive Programs

4 Applications

5 Conclusions

Source Code of a Recursive Program

Every recursive program computing a function f with domain a subset of Σ , is an instance of the following abstract scheme:

$$f.s = \mathbf{if} \ b.s \to q.s$$

 $\Box \ c.s \to h(f, M.s)$
 \mathbf{fi}

where

- s symbolizes the initial state of program f.
- conditions *b* and *c* correspond (initially) to all non-recursive and all recursive cases of its domain,
- q.s is the final value given by f in the non recursive cases
- h(f, M.s) involves at least one recursive invocation of f on a set of states M.s.

Associated Operator

Abstract Recursive Scheme

$$f.s = \mathbf{if} \quad b.s \to q.s$$
$$\Box \quad c.s \to h(f, M.s)$$
$$\mathbf{fi}$$

For a *relational operator* f corresponding to the program scheme above we may assume the existence of a relation Q and a relational operator h fulfilling the following for all relation R,

$$f.R = Q \cup h.R$$

with

(a)
$$QL \cap (h.L)L = C$$

(b) $h.O = O$

The Concept of Inductivity

The fact that the recursive program scheme above allows calculating the values of (program) function f by stages suggests both

- i) requiring the associated operator f to be *continuous* and
- ii) defining the following concept:

Inductivity

Given an operator f, a relation R and a sequence of conditions $\langle c_n \rangle_{n \ge 0}$, we say that f is *inductive* over R through the given sequence if

$$f.R \cap c_{n+1} = f(R \cap c_n)$$

for all $n \ge 0$.

Regularity Conditions

The regularity conditions we looked for are the following:

Definition of Regular Operators

A continuous operator f is *regular* if it fulfills the following *regularity conditions*:

There exist a relation Q and an operator h such that

(a)
$$f.R = Q \cup h.R$$
 for all relation R .

(b)
$$QL \cap (h.L)L = O$$

(c)
$$h.O = O$$

(d) h is inductive over *every fixed point* of f, through the sequence of conditions $\langle (f^n, O)L \rangle_{n>0}$.

The inductivity of h over any fixed point K of f through the ascending chain $\langle (f^m, O) L \rangle_{m>0}$ is equivalent to the inductivity of f over K through the same chain.

Inductivity of Regular Operators

Proposition 1

For a *continuous* operator f, satisfying regularity conditions (a), (b) and (c) and K fixed point of f, the following three properties are equivalent:

- (i) f is inductive over K through ascending chain $\langle (f^n, O)L \rangle_{n>0}$.
- (ii) $K \cap (f^n, O)L = f^n, O$ for all natural n.
- (iii) $K \cap \mu f L = \mu f$, and sequence $\langle f^n, O \rangle_{n>0}$ is stable.

Definition of a Stable sequence of relations

A sequence of relations $\langle R_n \rangle_{n \ge 0}$ is *stable* whenever

$$m < n \Rightarrow R_n \cap R_m L = R_m$$

for all natural numbers m and n.

Deterministic Programs are (easily) Regular

Inductivity condition is non restrictive for recursive programs defining (partial) functions: if in scheme equation

$$f.R = Q \cup h.R$$

Q is a *univalent* relation and h is *closed* on *univalent* relations; necessarily, f is also closed on these relations and μf becomes a partial function. Therefore,

• if every fixed point of f is univalent (at least on the domain of μf) then necessarily, all of them coincide with μf on $\mu f L$ and

• since the chain of *partial functions* f^n . O must be stable,

by last proposition f satisfies inductivity condition (d).

Proof of Proposition 1

(i) f is inductive over K through ascending chain $\langle (f^n, O)L \rangle_{n>0}$. (ii) $K \cap (f^n, O)L = f^n, O$ for all natural n. Proof of (i) \equiv (ii): " \Rightarrow " By induction on *n*. Case *n*=1 is easy. Suppose *n*>1. $K \cap (f^n, O)L$ $= \langle K \text{ fixed point of } f \rangle$ $f.K \cap (f^n.O)L$ $= \langle Hypothesis(i) \rangle$ $f(K \cap (f^{n-1}, O)L)$ = (Inductive hypothesis) $f(f^{n-1}, O)$ = $\langle \text{ Definition of } f^n \rangle$ fⁿ. 0

Proof of Proposition 1

(i) f is inductive over K through ascending chain $\langle (f^n, O)L \rangle_{n>0}$. (ii) $K \cap (f^n, O)L = f^n, O$ for all natural n. Proof of (i) \equiv (ii): " ⇐" $f(K \cap (f^m, O)L)$ $= \langle (ii) \rangle$ f.f^m.O $= \langle f \circ f^m = f^{m+1}; (ii) \rangle$ $K \cap (f^{m+1}, O)L$ $= \langle K \text{ fixed point of } f \rangle$ $f.K \cap (f^{m+1}.O)L$

Proof of Proposition 1

(ii)
$$K \cap (f^n, O)L = f^n O$$
 for all natural *n*.
(iii) $K \cap \mu fL = \mu f$, and sequence $\langle f^n, O \rangle_{n>0}$ is stable.
Proof of (ii) \equiv (iii):
" \Rightarrow " a)
 $K \cap \mu fL$
 $= \langle f \text{ continuous operator } \rangle$
 $K \cap (\bigcup_{m>0} f^m, O)L$
 $= \langle \circ \circ' \text{ and } \cap' \text{ distributes over } \cup \rangle$
 $(\bigcup_{m>0} K \cap (f^m, O)L)$
 $= \langle \text{Hypothesis (ii) } \rangle$
 $(\bigcup_{m>0} f^m, O)$
 $= \langle f \text{ continuous operator } \rangle$
 μf

Proof of Proposition 1

(ii)
$$K \cap (f^n. O)L = f^n. O$$
 for all natural n .
(iii) $K \cap \mu fL = \mu f$, and sequence $\langle f^n. O \rangle_{n>0}$ is stable.
Proof of (ii) \equiv (iii):
" \Rightarrow " b) Suppose $m < n$ then
 $f^n. O \cap (f^m. O)L$
 $= \langle (ii) \rangle$
 $K \cap (f^n. O)L \cap (f^m. O)L$
 $= \langle ((f^n. O)L \rangle_{n>0}$ ascending chain ; $m < n \rangle$
 $K \cap (f^m. O)L$
 $= \langle (ii) \rangle$
 $f^m. O$

Regular Recursive Schemes

Definition

Relation P is defined by a *regular recursive scheme* associated to operator f, whenever

- P is a relation representing a program, and
- $P = \mu f$ i.e. *P* is the *minimum solution* of the fixed point equation associated to a *regular operator f*.

If relation P represents a *program* and a relation S represents a *specification*, the expression $P \subseteq S$ means that program P meets specification S.

Correctness Criterion

Proposition 2

If *P* is a program defined by a *regular recursive scheme* associated to an operator *f* via equation $f.R = Q \cup h.R$ (i.e. $P = \mu f$) then, there exists an ascending chain of conditions $\langle b_n \rangle_{n \ge 0}$ with union equal to *PL*, $b_0 = QL$, and such that

$P \subseteq S \equiv Q \subseteq S \land (\forall n \mid n \ge 0 : P \cap b_n \subseteq S \Rightarrow h(P \cap b_n) \subseteq S)$

This proposition gives an induction scheme for proving that program P satifies S.

In fact, this scheme may be generalized to well founded relations on the classes determined by a covering on the domain of P.

Correctness Criterion

Partial Proof of prop. 2

Let $b_n = (f^{n+1}, O)L$ for all non negative *n*. The equivalence is proved as follows:

$$P \subseteq S$$

$$\equiv \langle P = \mu f ; \text{ definition of } b_n ; f \text{ regular }; \text{ prop. } 1 \rangle$$

$$(\bigcup n \mid n \ge 0 : P \cap b_n) \subseteq S$$

$$\equiv \langle \text{ Set Theory} \rangle$$

$$(\forall n \mid n \ge 0 : P \cap b_n \subseteq S)$$

$$\equiv \langle \text{ Induction on } n \rangle$$

$$P \cap b_0 \subseteq S \land (\forall n \mid n \ge 0 : P \cap b_n \subseteq S \Rightarrow P \cap b_{n+1} \subseteq S)$$

$$\equiv \langle P \cap b_0 = Q ; P = \mu f ; \text{ proposition } 1 \rangle$$

$$Q \subseteq S \land (\forall n \mid n \ge 0 : P \cap b_n \subseteq S \Rightarrow f(P \cap b_n) \subseteq S)$$

$$\equiv \langle f.R = Q \cup h.R \rangle$$

$$Q \subseteq S \land (\forall n \mid n \ge 0 : P \cap b_n \subseteq S \Rightarrow h(P \cap b_n) \subseteq S)$$

General Correctness Theorem

If P is a program defined by a recursive scheme associated to a monotonic operator f via equation $f.R = Q \cup h.R$, then, for all well founded set (\mathcal{C}, \Box) with \mathcal{C} a countable family of conditions with union equal to PL, and ' \Box ' a well founded relation on \mathcal{C} such that

(i)
$$(\forall u \in \mathcal{C} \mid : u \subseteq QL \lor u \subseteq PL \cap \overline{QL})$$

(ii)
$$(\forall u \in \mathcal{C} \mid u \subseteq PL \cap \overline{QL} : P \cap u \subseteq h(\bigcup v \mid v \sqsubset u : P \cap v))$$

we have the equivalence of the following two propositions:

a) Program P satisfies specification S.

b)
$$(\forall v \mid v \subseteq QL : P \cap v \subseteq S) \land$$

 $(\forall v \mid v \subseteq PL \cap \overline{QL} :$
 $(\forall u \mid u \sqsubset v : P \cap u \subseteq S) \Rightarrow h(\bigcup u \mid u \sqsubset v : P \cap u) \subseteq S)$

Applying the Correctness Theorem

Restricting the application of previous theorem to functions (like f) requires finding a well founded relation ' \Box ' on the domain of f for which

 $c.s \land t \in M.s \Rightarrow t \sqsubset s$ for all states s and t.

 ・

Besides this, regularity conditions above reduce to two (reasonable) conditions holding for all state $s \in \Sigma$:

1.
$$\neg$$
(*b.s* \land *c.s*)
2. *b.s* \Rightarrow *dom a.s*

Ackermann function

This function A(x, y) is defined for natural numbers x and y by

$$A(x,y) = \begin{cases} y+1 & \text{if } x=0 \\ A(x-1,1) & \text{if } y=0 \\ A(x-1,A(x,y-1)) & \text{otherwise} \end{cases}$$

This *function* is clearly defined by a regular inductive scheme. The usual lexicographic order relation on $\mathbb{N} \times \mathbb{N}$ (noted with ' \prec ') is a well founded relation satisfying the requirement given above:

$$\begin{array}{ll} (x-1,1) \prec (x,y) & \text{if } x \neq 0 \land y = 0. \\ (x,y-1), (x-1,A(x,y-1)) \prec (x,y) & \text{if } x \neq 0 \land y \neq 0. \end{array}$$

A Relational Theorem on the Correctness of General Recursive Programs Applications

McCarthy's 91 function

This function is defined for natural number x by

$$g.x =$$
if $x > 100 \rightarrow x - 10$
 $\Box x \le 100 \rightarrow g(g(x+11))$
fi

This recursive scheme is regular. Partial order ' \sqsubset ' on $\mathbb Z$ defined as

 $x \sqsubset y \equiv y \le 100 \land y < x$ for all integers x and y,

allows to apply our theorem. \square is a well founded relation such that

- if x > 100 then x is \square -minimal,
- $x+11 \sqsubset x$ if $x \le 100$ and
- $g(x+11) \sqsubset x$ if $x \le 100$.

A Relational Theorem on the Correctness of General Recursive Programs Applications

McCarthy's 91 function

If
$$g.x = \mathbf{if} \ x > 100 \rightarrow x - 10$$

 $\Box \ x \le 100 \rightarrow g(g(x+11))$
 \mathbf{fi}

we may prove by induction on (\mathbb{Z}, \Box) that for all integer x, g.x = f.x where

$$f.x = \mathbf{if} \ x > 101 \rightarrow x - 10$$
$$\Box \ x \le 101 \rightarrow 91$$
$$\mathbf{fi}$$

Since g.101 = 101 - 10 = 91 = f.101, by definition of f and g, it is enough to show that g.x = f.x for $x \le 100$.

- 3 Correctness of Regular Recursive Programs

4 Applications

A Relational Theorem on the Correctness of General Recursive Programs Conclusions

Final Conclusions

- We have found reasonable *regularity conditions* to ask of the code of a recursive program to prove it correct with respect to a given specification.
- (terminating) *Deterministic* recursive programs fulfill these regularity conditions.
- The correctness proof of a recursive program may be done by *induction on a well founded relation on its domain* induced by the values on which the program recurs (according to its code).
